SENSITIVITY EVALUATION AND OPTIMIZATION
OF THE IEEE 118-BUS POWER SYSTEM

J.W. Bandler, M.A. El-Kady and H.K. Grewal

Abstract

A single-line diagram and brief description of the IEEE 118-bus system is provided in this report. The system is extensively used in the application and verification of various analytical methods and computerized algorithms for power network analysis and planning. The complex Lagrangian method is employed to evaluate sensitivities of different network functions. These sensitivities have been verified by small perturbations about the nominal point. A minimum-loss problem is formulated and solved using the optimization package MINOS/AUGMENTED.

This work was supported by the Natural Sciences and Engineering Research Council of Canada under Grants A7239, A1708 and G0647.

The authors are with the Simulation Optimization Systems Research Laboratory and the Department of Electrical and Computer Engineering, McMaster university, Hamilton, Canada L8S 4L7.

M.A. El-Kady is also with Ontario Hydro, Toronto, Canada.

I. INTRODUCTION

The IEEE 118-bus system [1] is a standard, average size test network. It has been extensively used in a variety of steady-state analysis and planning studies. The power transmission network of the system comprises transmission lines, tap-changing-under-load transformers and phase-shifting transformers [2,3]. At some of the nodes, the static load is specified, which may be used as a means of controlling a given network function.

A single-line diagram of the system is provided which indicates load and generator buses, and their interconnections through transmission elements. The diagram is useful for investigating expansion plans, fault and contingency analysis, and real-time operations [4]. The generator bus with widest P, Q limits and/or largest generation is generally chosen to represent the slack bus and is declared as the last bus of the system.

The load flow problem of the system may be formulated in complex, rectangular or polar mode and can be solved by using an appropriate package [5-9]. In order to evaluate sensitivities of a real network function, various packages [5-7] can be used and the sensitivities supplied to gradient-type optimization routines. However, in this report we have presented the results obtained from the package XLF3 [6], which is capable of handling the complex turns ratio of phase-shifting transformers. The package can provide sensitivities w.r.t. bus-type control variables and adjustable control parameters of transmission elements, including the turns ratio and internal impedance of the transformers. A minimum-loss problem of the system is formulated and solved using the optimization package MINOS/AUGMENTED [10]. The various data files and the computer program listing are included in the Appendix.

II. GENERAL DESCRIPTION

The IEEE 118-bus system shown in Fig. 1 consists of load buses ($n_L = 64$), generator buses ($n_G = 53$) and a slack bus, usually indexed as the last bus ($n = 118$). The power transmission network of the system comprises lines ($n_T = 170$), tap-changing-under-load transformers ($n_t = 7$) and phase-shifting transformers ($n_p = 2$). At some of the buses ($n_S = 14$), switchable shunt reactors/capacitors are provided. The buses with zero demand ($n_d = 10$) are considered as load buses and are included in n_L .

The power system has been frequently investigated as a standard test network in large scale optimal power flow and planning studies [11]. The load flow problem has been formulated and solved by implementing different algorithms [5-9] from a flat voltage profile of the system. We describe data files which are relevant to package XLF3. These files are available under the charge RJWBAND [12] and can be accessed by the following commands

/GET, B118FVA/GR.

/GET, B118FVB/GR.

The difference between these files lies only in the values of the control variables associated with some of the generator buses listed in Table I and it appears that B118FVB is an optimized version of B118FVA. The solution files are also available under the same charge, namely, B118SVA and B118SVB, respectively. All the values in these various files are in the per unit system.

III. SENSITIVITY EVALUATION USING PACKAGE XLF3

The package XLF3 [6] has been designed to handle the load flow equations in complex mode and provide sensitivities of a general real function with respect to network controls listed in Table II. However, it is the user's responsibility to supply the right-hand-side vector of the adjoint system of a function of interest. We present some examples to illustrate the use of this package.

Example 1

We consider the voltage magnitude at a load bus ($\ell = 35$) given by

$$f_1 = |V_{35}| = (V_{35} V_{35}^*)^{1/2}. \quad (1)$$

The non-zero element of df_1/dV is given by

$$\frac{df}{dV_{35}} = \frac{0.5 V_{35}^*}{|V_{35}|}. \quad (2)$$

The sensitivities of this function with respect to several control variables are provided in Table III.

Example 2

Another network state associated with a load bus is the bus voltage angle and we consider a function given by

$$f_2 = \delta_{16} = \tan^{-1} \left[\frac{V_{16} - V_{16}^*}{j(V_{16} + V_{16}^*)} \right]. \quad (3)$$

The function is dependent on complex voltage V_{16} and its conjugate, hence the only non-zero element of df_2/dV is given by

$$\frac{df_2}{dV_{16}} = -j \frac{0.5}{V_{16}}. \quad (4)$$

The sensitivities of f_2 with respect to various control variables are provided in Table IV.

Example 3

Next, we consider reactive power at a generator bus ($g = 72$) given by

$$f_3 = Q_{72} = \frac{S_{72} - S_{72}^*}{2j}. \quad (5)$$

Using Fig. 1 (page 55), we write the current injected at this bus in the form

$$I_{72} = Y_{72,72} V_{72} + Y_{72,24} V_{24} + Y_{72,71} V_{71} \quad (6)$$

and the function f_3 can be expressed as

$$f_3 = \frac{V_{72} I_{72}^* - V_{72}^* I_{72}}{2j}. \quad (7)$$

The variables involved in (7) are complex voltages at buses 24, 71 and 72 and their complex conjugates. Hence the non-zero elements of vector df_3/dV are given by

$$\frac{df_3}{dV_{24}} = j0.5 Y_{72,24} V_{72}^*, \quad (8)$$

$$\frac{df_3}{dV_{71}} = j0.5 Y_{72,71} V_{72}^*, \quad (9)$$

and

$$\frac{df_3}{dV_{72}} = j0.5 [(Y_{72,72} - Y_{72,72}^*) V_{72}^* - (Y_{72,24}^* V_{24}^* + Y_{72,71}^* V_{71}^*)]. \quad (10)$$

The sensitivities of this function are provided in Table V.

Example 4

The real power at the slack bus ($n = 118$) is considered in this example, which can be expressed in the form

$$f_4 = P_n = \frac{S_n + S_n^*}{2}. \quad (11)$$

From Fig. 1, the various buses connected to the slack bus are 47, 49, 68, 70, 75 and 77. Using an expression for the injected current similar to (6), we can express the non-zero elements of df_4/dV in a straightforward manner. These elements are

$$\frac{df_4}{dV_k} = 0.5 \left(Y_{nk} V_n^* + \delta_{kn} \sum_{i=1}^n Y_{ni}^* V_i^* \right) \quad (12)$$

where

$$\delta_{kn} = \begin{cases} 0 & \text{for } k \neq n \\ 1 & \text{for } k = n \end{cases}$$

The sensitivities of this function are provided in Table VI.

We have considered δ_g ($g = 72$) and Q_n also, in a manner similar to Examples 2 and 3, respectively. Their sensitivities are displayed in Tables VII and VIII. These results have been verified by small perturbations about the nominal point.

IV. FORMULATION AND SOLUTION OF A MINIMUM-LOSS PROBLEM

The minimum-loss problem of a power system is a constrained minimization problem where the cost function is the total transmission active power loss in the system. The problem is routinely solved with multiple objectives [11,13]. For an n-node system, the function is given by

$$f = \sum_{i=1}^n P_i, \quad (13)$$

where P_i is the net real power injected at the i th node [14]. The load flow equations are included as equality constraints and the bounds on other system variables \mathbf{x} and/or \mathbf{u} are represented as inequality constraints. The problem, in general, is stated as

minimize f

subject to

$$\mathbf{h}(\mathbf{x}, \mathbf{u}) = \mathbf{0}$$

and

$$\mathbf{g}(\mathbf{x}, \mathbf{u}) \geq \mathbf{0}.$$

We consider the generator-bus control variables with the bounds

$$0.9 \leq |V_g| \leq 1.1$$

$$0 \leq P_g \leq 1.30 P_{g(nominal)}$$

for all g . The specifications for the problem are displayed in Table IX. The results from the optimization package MINOS/AUGMENTED are summarized in Table X. A brief description of the package and computer program listing are provided in the Appendix.

V. CONCLUSIONS

The IEEE 118-bus system has been described briefly. The complex Lagrangian method has been employed to evaluate sensitivities of various network functions. The control variables considered are load bus real and reactive powers, generator bus voltage magnitudes and real powers, line conductances and susceptances, turns ratios and internal impedances of

phase-shifting and tap-changing-under-load transformers. The sensitivities have been verified by small perturbations about the nominal point. A minimum-loss problem for the system has been formulated and solved by an optimization package, which is capable of verifying the objective gradients. Any other optimization problem may be attempted in a similar way. For corridor selection or line contingency the single-line diagram may prove quite useful.

APPENDIX

MINOS/AUGMENTED (ALIAS MINOS VERSION 4.0)

This is a general purpose nonlinear programming system developed by Murtagh and Saunders [10]. The system is especially designed for solving large-scale optimization problems involving sparse linear and nonlinear constraints [11].

The solution process consists of a sequence of "major iterations". At the start of each major iteration, the nonlinear constraints are linearized at the current point and the cost function is modified. This includes a quadratic penalty function and an estimation of the Lagrange multipliers for the linearized constraints. The linearly constrained subproblems are then solved in a sequence of "minor iterations" using the reduced-gradient algorithm shown in Fig. 2 (page 56).

The data for an optimal power flow problem is supplied by means of the SPECS file, the MPS file and the power network data file.

DESCRIPTION OF THE FILES

Unit Number	Description
1	<p>SPECS data containing a list of keywords and values defining various optimization parameters.</p> <p>MPS data containing linear objectives and constraints, inequalities and right-hand-sides of constraints, upper and lower bounds for variables and constraints, and the definition of the starting point.</p>
3	B118SVB describing the transmission elements and the load flow solution of the IEEE 118-bus system. All the values contained in this file are in the per unit system.
6	Output file containing listing of the SPECS and MPS data, parameters, iteration log, solution and error messages.
9	Scratch file used during input of the SPECS file and for storing ROW and COLUMN names from the MPS data.
10	OLD BASIS FILE intended for restarting the solution of the problem at a point reached by an earlier run ("warm start").
11	NEW BASIS FILE stored for a subsequent run of the problem.
